

likewise be absent. If, for example, there are no chestnuts, there will also be no palominos even if the cream gene is present.

Likewise, in breeds where all individuals have a specific modifier, base color will influence what is possible. All Fjords are dun, for example. But because Fjords are also genetically chestnut, black and bay, we see the full range of red duns, grullas and yellow duns. If one or more of the base colors was missing in the breed, then only the modified form of the available colors would be present. Tarpan, for example, are also uniformly dun. They are also uniformly grulla, because the base colors of chestnut and bay are not available. A red dun Tarpan would therefore be an unrealistic model.

For this reason, it is important to know which base colors are present (and common or uncommon) in each breed. Chart 1 gives information on the possible base colors for some of the more popular breeds in the model show ring. When the base colors are found only in conjunction with a specific modifier, they are noted as "always" modified. For those breeds that are only bay, or black or chestnut, they are noted as "never" modified.

Modifiers

All the remaining horse colors are the result of genes that modify the three base colors. The following charts indicate which modifiers are found in each breed. The modifiers are broken down into:

- 1) White hairs, 2) Dilutions and 3) Patterns of white.

Modifiers That Add White Hairs

The first group of modifiers are those that distribute white hairs through the coat. The most common of these is grey. Many horsemen mistakenly think of grey as a separate color, but in fact it is a modifying gene that progressively lightens the horse's original color. All greys, therefore, are also either chestnut, black or bay. True roans have white hairs intermixed with their base color, but unlike greys they do not get lighter with age. They also have dark points, including the head, which has lead many to refer to them as "dark-headed roans". Finally there is the rabicano pattern, which results in roaning on the flank (sometimes

forming a brindled pattern) and a skunk tail. Because this pattern is often quite subtle and can be hard to see in photographs, many breeds will have this column noted simply as "unknown". (Chart 2)

Genes That Dilute Color

There are four known dilution genes found in horses: cream, dun, silver and champagne. Although cremellos and perlinos are the result of two cream genes (and are therefore possible whenever a breed has the cream gene), they are given a separate column because so many registries restrict or penalize the color. (Chart 3)

Patterns of White

These are the genes that create distinct white patterns on the horse. Included are the genes that create distinct white patterns on the horse. Included are the genes that create distinct white patterns on the horse. Included are the genes that create distinct white patterns on the horse. Included are the genes that create distinct white patterns on the horse. Note that patterns designated as Prohibited are usually only denied
